

Remarks

The specification has been amended with the insertion of the headings of each section of the specification which was inadvertently omitted from the previously submitted preliminary amendment. The abstract has been amended as suggested. Independent claim 1 also has been amended to provide appropriate antecedent basis for several of the terms stated, and the grammar of the claim has been remedied.

Applicants acknowledge with appreciation the indication of the allowability of claims 4 through 7, and respectfully request reconsideration of the rejection of claims 1 through 3 and 8 through 14 in view of the following comments.

The claimed invention relates to a motor vehicle provided with a manual transmission, and has for its principal objective a reduction of the stress incurred by the clutch during idling and start-up of the engine. Such stress is alleviated by reduction of engine torque during such intervals.

As amended, each of the claims provides that when at least one approval criterion is satisfied for the engine torque which is dependent on the driving state of the vehicle, a default engine torque which can be reduced relative to the setpoint engine torque required by the position of the accelerator of the vehicle is stipulated, and the default engine torque is determined as a function of at least one engine characteristic.

The Hess et al patent principally relied upon does not relate to a motor vehicle with a manual transmission and particularly to the problem of undue stress incurred by the clutch of such vehicle during idling and start-up. It relates to a method and system for the rapid change of torque values responsive to various interventions such as the operation of climate control devices and the like. It

does not disclose or teach a reduction of torque below a setpoint torque during idling and start up for the purpose of avoiding undue stress incurred by clutch materials.

In view of the forgoing, it respectfully is requested that the rejection of claims 1 through 3 and 8 through 14 be withdrawn, such claims be allowed and further that the application be passed to issue.

The Director is hereby authorized to charge any deficiency in the fees filed, asserted to be filed or which should have been filed herewith, or credit any overpayment, to our Deposit Account No. 14-1437, under Order No. 8369.028.US0000

Respectfully submitted,

**NO NEW MATTER IS INTRODUCED**

Method for Controlling the Engine of a Motor Vehicle Having  
a Manual Transmission

The invention relates to a method for controlling the engine of a motor vehicle having a manual transmission.

Background of the Invention

In motor vehicles with manual transmissions there is a mechanical clutch which can normally be actuated by way of a foot pedal by the driver of a motor vehicle during a shifting process which takes place by manual actuation of the manual transmission to interrupt the flow of power between the engine and transmission of the vehicle. At high engine speed in idle and in a start-up process which takes place at high engine speed (for example, in a racing start with a slipping clutch) very high frictional work is transmitted to the clutch due to the large difference in speed between the engine and transmission. This leads to very strong thermal loading of the clutch; this results in premature clutch wear, especially for high-torque and high-pickup, high-revolution engines with four-wheel drive.

The object of the invention is to devise a method for engine control of a motor vehicle with a manual transmission, in which the adverse effects on the clutch, especially in the start-up process and in idling of the motor vehicle, are avoided.

This object is achieved as claimed in the invention by the characterizing feature of claim 1.

Advantageous embodiments of the invention are a component of the other claims.

### Summary of the Invention

As claimed in the invention, in In a motor vehicle with manual transmission in which there are no means for direct determination of the engaged gear, a reduction of the setpoint engine torque required by the driver by actuating the accelerator is allowed in particular for limiting the engine torque as long as at least one definable (applicable) approval criterion for the driving state of the motor vehicle is satisfied. In this connection at least one approval criterion dependent on the driving speed of the motor vehicle is used, especially a definable, applicable speed threshold not being reached by the driving speed of the motor vehicle; in this connection, preferably a value in the range from 30 km/h to 40 km/h, or a value below 40 km/h, for example a value of approximately 35 km/h, is defined as the speed threshold for the driving speed of the motor vehicle. Accordingly, at a driving speed of zero of the motor vehicle (when the vehicle is idling) or at a driving speed of the vehicle which is less than the speed threshold (in the process of the vehicle's starting up), instead of the setpoint engine torque required by the driver by actuating the accelerator, especially to limit the engine speed a default engine torque is determined which is reduced relative to the setpoint torque under certain assumptions. Optionally another approval criterion (especially in the process of the vehicle's starting up) is the applicable delay time, i.e., a possible reduction of the setpoint engine torque required by the driver by actuating the accelerator and thus the stipulation of a default engine torque which may deviate therefrom is approved only after a certain time interval has elapsed after recognition of the process of the vehicle's starting up. This delay time (for example 500 ms) can be used especially in motor vehicles with a slow build-up of engine power or engine torque as the approval criterion, for example in motor vehicles with turbochargers in which a slow build-up of the charging pressure takes place.

The default engine torque is determined in this process depending on at least one engine characteristic, preferably the engine speed on the one hand and the quotient of the engine speed and the driving speed of the vehicle on the other are used as engine characteristics. To generate the default engine torque, a torque factor to which values in the range from 0 to 1 are assigned is applied to the setpoint engine torque; the default engine torque thus deviates from the setpoint engine torque and is reduced relative to the setpoint engine torque if the torque factor does not reach 1; this is preferably the case when the engine speed of the vehicle exceeds a definable speed threshold (for example, a value of

4600 rpm is defined as the speed threshold) and when the quotient of the engine speed and the driving speed of the vehicle is within a definable value range (for example, between  $100 \text{ min}^{-1}/\text{km/h}$  and  $500 \text{ min}^{-1}/\text{km/h}$ ). The torque factor can be determined from the characteristic map in which the engine characteristics used, preferably the engine speed and the quotient of the engine speed and the driving speed of the vehicle, are displayed. A default engine torque which has been reduced compared to the setpoint engine torque (for a torque factor which drops below 1) is ordinarily implemented by an action which influences the engine torque, especially by an action on the throttle valve and/or ignition and/or the fuel injection of the vehicle.

Preferably, with this process, without the requirement of explicit recognition of the engaged gear, a significant reduction of the stress on the clutch and thus avoidance of overloads on the clutch can be ensured by limiting the engine torque and accordingly the engine speed both when the vehicle is idling and also when the vehicle is starting up. In racy start-up maneuvers, especially in the case of starting up with high speed and load, adverse effects on agility, acceleration behavior or driving comfort of the vehicle are avoided based on the uniform influence on the default engine torque as a result of the engine characteristics engine speed and driving speed which are preferably used and as a result of avoiding sudden changes of torque limitation when the gears are recognized and changed. When the vehicle is idling the limitation of engine torque and accordingly the engine speed can be used for acoustic purposes.

~~In conjunction with the drawings one exemplary embodiment of the invention will be explained.~~

#### Brief Description of the Drawings

- FIG 1        shows a block diagram of the torque control,
- FIG. 2        shows the variation of the position of the accelerator and throttle valve as a function of time in the start-up process,
- FIG. 3        shows the variation of various engine characteristics in the start-up process as a function of time.

### Detailed Description of the Preferred Embodiment of the Invention

FIG. 1 shows a block diagram of an engine control which influences the start-up process of a vehicle with a manual transmission.

Influencing the setpoint engine torque  $M_s$  required by the driver of the vehicle by actuating the accelerator (see FIG. 2) and thus the stipulation of a default engine torque ( $M_v$  ( $M_v \leq M_s$ )) which may have been reduced in comparison here is allowed only when at least one approval criterion is met. The approval criterion to be met is for example the start-up or initial rolling of the vehicle (driving speed  $v$  of the vehicle  $> 0$ ; this is checked by means of a comparator 4), the progression of the delay time  $\tau$  (the delay time  $\tau$  of for example 500 ms is set by the delay element 5) and failure to reach a speed threshold  $v_s$  (driving speed  $v$  of the vehicle  $<$  speed threshold  $v_s$  of for example 35 km/h; this is checked by means of the comparator 3). When all approval criteria are met, at the output of the logic element 7 a corresponding logic signal is delivered to the control line 9 and actuates the switching element 2 which switches from the input line 9 (stipulation of a default torque  $M_v$  at the output 8 of the switching element 2 is blocked) to the input line 10 (stipulation of a default torque  $M_v$  at the output 8 of the switching element 2 is cleared). By multiplication of the setpoint engine torque  $M_s$  by the torque factor  $MF$  ( $MF \leq 1$ ) a default torque  $M_v$  is generated which is at most as large as the setpoint engine torque  $M_s$  under certain circumstances, but smaller than the setpoint engine torque  $M_s$  (no reduction of the setpoint engine torque  $M_s$  at  $MF = 1$ ; reduction of the setpoint engine torque  $M_s$  at  $MF < 1$ ). To determine the torque factor  $MF$  with the input line 10 of the switching element 2 isolated, the two engine characteristics speed  $n$  on the one hand and the quotient  $Q$  of engine speed  $n$  and the driving speed  $v$  of the vehicle on the other are used and are sent as input values to the characteristic map 1, at the output of which the torque factor  $MF$  ( $MF \leq 1$ ) is output to the input line 10. For example, the torque factor  $MF$  is only then different from 1 ( $MF < 1$ ) and in this way by way of the output 8 of the switching element 2 causes an action on the setpoint engine torque  $M_s$  to limit the engine speed, when the engine speed  $n$  exceeds the speed threshold  $n_s$  (for example a value of 4600  $\text{min}^{-1}$  is stipulated as the speed threshold) and the quotient  $Q$  of the engine speed  $n$  and the driving speed  $v$  of the vehicle is within a certain value range (for example, this range of values from 150  $\text{min}^{-1}/\text{km/h}$  to 500  $\text{min}^{-1}/\text{km/h}$  is stipulated; this corresponds approximately to the range of first gear of a conventional manual transmission). The action to reduce the setpoint engine torque  $M_s$  to the default

torque  $M_v$  for a torque factor MF less than 1 ( $MF < 1$ ) can take place for example by way of the throttle valve or the injection instant or the ignition instant.

FIGS. 2 and 3 shows the variation of certain engine characteristics of a motor vehicle with a manual transmission in a racing start (start-up of the vehicle at full throttle and with clutch depressed) as a function of time. FIG. 2 shows the variation of the position of the accelerator dictated by the driver as a function of time (curve (a) as a measure for the setpoint engine torque  $M_s$ ) and the position of the throttle valve (curve (b) as a measure of the default torque  $M_v$ ), in FIG. 3 the variation of the driving speed  $v$  (curve (c) as a function of time), the engine speed  $n$  (curve (d)), of the quotient  $Q$  of the engine speed  $n$  and the driving speed  $v$  (curve (e)), and of the torque factor (curve (f)).

At time  $t_1$  before the vehicle starts off, for a racing start the accelerator is completely depressed (curve (a)) and accordingly the throttle valve is completely opened (curve (b)), at the same time the clutch pedal is depressed. The engine speed  $n$  (curve (d)) rises to a critical value of for example  $5800 \text{ min}^{-1}$  which is above the speed threshold  $n_s$  of for example  $4600 \text{ min}^{-1}$ .

At time  $t_2$  when the vehicle starts up (starting to roll) the clutch is suddenly or gradually released, the accelerator (curve (a)) remains completely depressed and the throttle valve (curve (b)) is completely (100%) opened (full throttle), by which the driving speed  $v$  (curve (c)) assumes a non-zero value ( $v > 0$ ). The engine speed  $n$  (curve (d)) remains at a value above the speed threshold  $n_s$  (for example,  $4600 \text{ min}^{-1}$ ). As a result of the high rpm difference between the engine and transmission of the vehicle, this can lead to thermal overloading of the clutch and thus to wear (failure) of the clutch.

At time  $t_3$ , immediately after the vehicle starts up however limitation of the engine torque  $M$  from the setpoint engine torque  $M_s$  to the default torque  $M_v$  is effected however by way of the torque factor MF, since on the one hand the approval criteria for the default torque  $M_v$  are satisfied (driving speed  $v > 0$  and driving speed  $v$  is less than the speed threshold  $v_s$  of for example  $35 \text{ km/h}$ ), a delay time  $\tau$  after time  $t_2$  (start-up of the vehicle) is for example not stipulated ( $\tau = 0$ ), and on the other hand, based on the values of the engine characteristics, engine speed  $n$  and quotient  $Q$  of the engine

speed  $n$  and the driving speed  $v$ , as the input quantities of the characteristic map 1 (in particular, the engine speed  $n$  exceeds the torque threshold  $n_s$  of  $4600 \text{ min}^{-1}$ , while the quotient  $Q$  is in a stipulated value range which is characteristic of first gear), a torque factor different from 1 is output by the characteristic map 1 ( $MF \leq 1$ , for example the minimum value of  $MF$  is approximately 0.3). In this way the completely opened throttle valve (throttle valve opening 100%) is again partially closed (opening of the throttle valve  $< 100\%$ , for example approximately 20% opening of the throttle valve) and therefore a default torque  $M_v$  reduced compared to the setpoint engine torque  $M_s$  is delivered as the engine torque; this also causes a reduction of the engine speed  $n$  which accordingly drops below the speed threshold  $n_s$  of  $4600 \text{ min}^{-1}$ .

At time  $t_4$ , based on the now altered values of the engine characteristics engine speed  $n$  and quotient  $Q$  of the engine speed  $n$  and driving speed  $v$  as the input quantities of the characteristic map 1 (especially by reducing the engine speed  $n$ , which thus again falls below the speed threshold  $n_s$  of  $4600 \text{ min}^{-1}$ ) again the value 1 for the torque factor  $MF$  is output by the characteristic map 1 ( $MF = 1$ ), by which the throttle valve (curve (b)) is opened again according to the position of the accelerator (curve (a)) (opening of the throttle valve to 100%) and the default torque  $M_v$  which corresponds to the setpoint engine torque  $M_s$  is delivered as the engine torque.

At time  $t_6$ , when the speed threshold  $v_s$  of for example  $35 \text{ km/h}$  is reached for the driving speed  $v$ , the approval criterion for the stipulation of the default torque  $M_v$  is no longer satisfied, so that starting from this instant  $t_5$  the stipulation of the default torque  $M_v$  is deactivated. In this way the switching element 2 as shown in FIG. 1 is switched to the input line 9 and the setpoint engine torque  $M_s$  required by the position of the accelerator is output on the output line 8 of the switching element 2.
